KENTUCKY BURLEY TOBACCO VARIETY TESTS - SUMMARY

1964-69

J. H. Smiley, A. M. Wallace, George Everette, G. B. Collins C. C. Litton, and P. D. Legg²

The objective of the Kentucky Burley Tobacco Variety Tests is to provide information on the relative performance of burley varieties, hybrids, and breeding lines. The information on varieties and hybrids may be used by farmers, seedsmen, research workers, and extension personnel as an aid to the selection of the variety or hybrid which performs best in a given area. The tests are part of the University of Kentucky Agricultural Experiment Station program to evaluate new breeding lines which may become candidates for varietal release.

METHODS

An expanded program of variety testing began in Kentucky in 1968. In addition to the tests at the University of Kentucky Agricultural Experiment Station at Lexington, tests were conducted on the farms of 11 cooperating tobacco growers throughout the state in 1968 and 12 locations in 1969. The locations (Fig. 1) were selected to represent the burley tobacco producing areas of Kentucky.

With one exception, each test was conducted on a disease-free soil and consisted of 15 entries in 1968 and 13 entries in 1969 in 1/50 acre plots replicated three times. Fertilizer was applied to each plot at the recommended rates based on soil tests. In 1968 thirty-three varieties, hybrids, and breeding lines were tested. Some were tested at all locations, but all tests did not contain the same varieties. In 1969, with a few exceptions, all tests consisted of the same entries.

RESULTS AND RECOMMENDATIONS

A summary of the performance of seven of the more widely grown standard varieties and hybrids is given in Table 1. Average yields are shown on tests conducted at Lexington in 1964-69, at Princeton 1965-67, and in on-farm tests at four locations in 1968 and nine locations in 1969.

The relative performance of four of the black shank resistant varieties and hybrids and Ky 14 is given in Table 2. Average yields are shown for tests conducted at Lexington 1965–1968, at Princeton 1964–1967, and in on-farm tests at four locations in 1968 and ten locations in 1969. Included in Table 2 are yields of these varieties and hybrids grown in 1969 on a black shank infested soil.

¹Cooperative investigations of the Kentucky Agricultural Extension Service, the Kentucky Agricultural Experiment Station, Lexington, Kentucky and the Crops Research Division, Agricultural Research Service, U. S. Department of Agriculture.

²Associate Extension Professor; Research Specialist; Extension Specialist; Associate Professor; Research Agronomist, Crops Research Division, ARS, USDA; Research Geneticist, Crops Research Division, ARS, USDA, respectively.

These variety test results should help farmers decide which varieties or hybrids to grow. Note that certain varieties performed well at some locations but not as well at others. However, varieties do not always perform the same, relative to each other, year after year at the same locations. For example, in Caldwell county in 1968, Ky 10 yielded 350 pounds per acre more than Ky 14, but in 1969 Ky 14 yielded 183 pounds per acre more than Ky 10.

In selecting the best variety for a given situation, an important point for consideration is that of disease. If diseases are a factor, selection of the proper variety may mean the difference between a good yield of desirable tobacco or a crop failure. Table 5 gives the degree of resistance to diseases of the more important standard varieties and hybrids tested in Kentucky.

For land infested with black root rot or fusarium wilt (or both), Ky 14 or Ky 12 is recommended. If wildfire is a problem, Ky 14, Ky 12, or Burley 21 (B 21) is recommended.

Black shank is one of the hardest tobacco diseases to control without reducing potential yield. The best control is to eliminate the organism from the farm by long-cycle rotation and good sanitation practices. If, however, sufficient land is not available for crop rotation or if rotation does not control black shank, then the use of a resistant variety or hybrid is recommended.

Two races of black shank are found in Kentucky. Race 0 is the most common, while race 1 is found on only a few farms. Satisfactory control of race 0 can be obtained from the use of a hybrid of L-8, but control of race 1 is more difficult. Varieties Burley 37 (B 37) and Burley 49 (B 49) are moderately resistant to both races, but they have other disadvantages. Both varieties have a low level of resistance to fusarium wilt, and B 37 is susceptible to mosaic. B 49 is late maturing and has relatively small leaves. However, if it is necessary to use a field infested with black shank and it is not known which race is present, then the use of B 37 or B 49 is a safeguard against a crop failure.

To determine which race of black shank organism is present in a field, grow a stick row of one of the L-8 hybrids such as MS Ky 12 x L-8 or MS B 21 x L-8. If these hybrids do not become diseased, race 0 is present and the next year the entire field can be grown in one of the black shank resistant hybrids.

The choice of which black shank resistant hybrid to grow for the control of race 0 should be based on other disease resistances needed. For example, MS Ky $12 \times L-8$ is resistant to the major diseases; mosaic, fusarium wilt, black root rot, and wildfire, as well as race 0 of the black shank fungus.

CHARACTERISTICS OF SOME VARIETIES

Kentucky 10

Ky 10 is a rather short, compact, stand-up type, high-yielding variety of fair quality. It has a small percentage of the plants which are slow growing because of an abnormally prolific root system (hair root). It matures 7-10 days later than B 21 and, when cut immature, the leaves tend to cure with green spots.

Kentucky 12

Ky 12 is a stand-up type, high-yielding variety with fair-to-good quality. It has shorter leaves than other varieties, but there are more of them. The leaves will be longer if plants are topped early (when half of the plants are in bloom) and to 22-25 leaves per plant. It is a late-maturing variety that is most useful where severe black root rot and fusarium wilt are problems.

Kentucky 14

 $\underline{\mathrm{Ky}\ 14}$ is a stand-up type, good-yielding variety with good quality. The leaves are approximately the same length as those of B 21 but a little wider. The leaf number and plant height are about the same as those of B 21. It matures about 5-7 days later than B 21. There is good retention of bottom leaves on the stalks before and during harvest.

Burley 21

<u>B 21</u> is an extreme stand-up type, good-yielding variety of high quality leaf. The plants are early and vigorous. It is one of the easier varieties to work (cultivate, prime, spray) because of its extreme stand-up qualities. There is a tendency for leaves to drop from the stalks in this variety under some conditions, especially when grown in a shallow, thin, compact soil or during a dry season.

Burley 37

B 37 is moderately resistant to both races of black shank. It is a stand-up type, fair yielding, good quality, broadleaf, uniformly maturing variety.

Hybrids

The Kentucky Agricultural Experiment Station released male sterile B 21 to seedsmen in 1959. The purpose was to encourage the production of hybrids with levels of black shank resistance not available in standard varieties. Seed producers have used the male sterile B 21 as the foundation of the present burley hybrid program.

The combined names of the two parents used in making the hybrid are used as the name of the hybrid and are printed on each seed package offered for sale. No yield differences in reciprocal crosses in the burley hybrids have been found.

Most hybrids offered for sale will have MS B 21 as one of the parents. This should improve smoking quality and acceptance of the leaf. MS Ky $12\,\mathrm{x}$ L-8 should be more useful than MS B $21\,\mathrm{x}$ L-8 where black root rot or fusarium wilt is a problem.

A hybrid may have a lower degree of resistance to a certain disease than the more resistant parent. For example, the MS B 21 - Ky 10 hybrid will have less black root rot resistance than Ky 10.

Yield (pounds per acre) of seven burley tobacco varieties and hybrids tested at Lexington 1964-1969, at Princeton 1965-1967, and in on-farm tests at four locations in 1969. Table 1.
